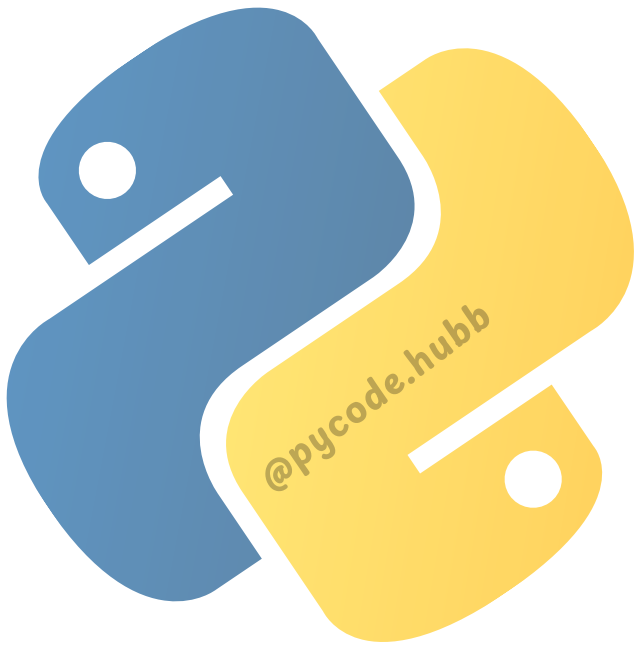
```
my_string = "Hello World!"
```



PYTHON STRINGS

Basic to Advance

The only Cheat Sheet You Need!

python™

NEXT

String Creation

```
# Creating strings using single quotes, double quotes, and triple quotes (multiline).
single_quote = 'Hello'
double_quote = "Dude"
multiline = '''Follow ↓ \nPycode.Hubb'''  # Multiline string using triple quotes

# Printing the results
print(single_quote)
print(double_quote)
print(multiline)
```

```
Hello
Dude
Follow ↓
Pycode.Hubb
```

String Indexing

```
s = "Python"

# Accessing characters using indexing
print(s[0])  # First character
```

```
P
```

String Slicing

```
# Slicing substrings
print(s[1:4])  # Substring from index 1 to 3
print(s[:5])   # Substring from start to index 4
print(s[::2])  # Every other character
```

```
yth
Pytho
Pto
```

Concatenation and Repetition

```
# Concatenating strings using + and repeating strings using *
concatenated = 'Follow' + ' ' + 'Pycode.Hubb'
repeated = 'Hi! ' * 3

# Printing the results
print(concatenated)  # Concatenated string
print(repeated)      # Repeated string
```

```
Follow Pycode.Hubb
Hi! Hi! Hi!
```

String Methods

```
s = "  Follow Pycode.Hubb!  "
```

lower() method

```
# Convert to lowercase
print(s.lower())  # Convert to lowercase
```

```
  follow pycode.hubb!
```

strip() method

```
# Strip leading and trailing spaces
print(s.strip())  # Remove leading/trailing spaces
```

```
Follow Pycode.Hubb!
```

replace() method

```
# Replace substring
print(s.replace('Follow', 'Subscribe'))  # Replace 'Follow' with 'Subscribe'
```

```
  Subscribe Pycode.Hubb!
```

split() method

```
# Split string by spaces
print(s.split())  # Split string by spaces
```

```
['Follow', 'Pycode.Hubb!']
```

startswith() method

```
# Check if the string starts with 'Follow'
print(s.startswith('Follow'))  # Check if starts with 'Follow'
```

```
False
```

endswith() method

```
# Check if the string ends with 'world!'
print(s.endswith('Pycode.Hubb!'))  # Check if ends with 'Pycode.Hubb!'
```

```
False
```

String Formatting

```
name = "Akash"
age = 29
```

using f-string

```
# Using f-string formatting
formatted_f = f"My name is {name} and I am {age} years old."
print(formatted_f)  # f-string formatting
```

```
My name is Akash and I am 29 years old.
```

using .format()

```
# Using .format() method
formatted_format = "My name is {} and I am {} years old.".format(name, age)
print(formatted_format)  # .format() method
```

```
My name is Akash and I am 29 years old.
```

using old-style %

```
# Using old-style % formatting
formatted_old_style = "My name is %s and I am %d years old." % (name, age)
print(formatted_old_style)  # Old-style formatting
```

```
My name is Akash and I am 29 years old.
```

Escape Sequences

```
# Using escape sequences like newline (\n), tab (\t), backslash (\\), and quotation marks
escaped_string = "Hello\nWorld\tPython\\is\"fun\""
print(escaped_string)  # Printing string with escape sequences
```

```
Hello
World	Python\is"fun"
```

String Comparison

```
# Comparing strings using ==, <, and other comparison operators
comparison1 = 'apple' == 'apple'  # True, strings are equal
comparison2 = 'apple' < 'banana'  # True, 'apple' is lexicographically smaller than 'banana'

# Printing the results
print(comparison1)  # True
print(comparison2)  # True
```

```
True
True
```

String Validation

```python
s = "12345"

# Checking if the string contains only alphabetic, numeric, or alphanumeric characters
print(s.isalpha())  # False, as the string contains only digits
print(s.isdigit())  # True, as the string contains only digits
print(s.isalnum())  # True, as the string contains only alphanumeric characters
```

```
False
True
True
```

Regular Expressions (Regex)

```python
import re

# Using regular expressions to find digits in a string
digits = re.findall(r'\d+', 'abc123def456')  # Finds and returns digits as a list

# Printing the result
print(digits)  # ['123', '456']
```

```
['123', '456']
```
